Pheromones are chemicals capable of acting outside the body of the secreting individual to impact the behavior of the receiving individual. (5)

Pheromones: Chemistry, Structure and Functions

Pheromone, any endogenous chemical secreted in minute amounts by an organism in order to elicit a particular reaction from another organism of the same species. Pheromones are widespread among insects and vertebrates; they are also found in crustaceans but are unknown among birds. The chemicals may be secreted by special glands or incorporated in other substances, such as urine.

Scientists in Osmology have determined that both sexes are attracted to each other through chemical messengers. These chemicals, pheromones, stimulate sexual arousal, desire, hormone levels, and even fertility when released. Pheromones are detected through smell and are produced through sweat, saliva, and urine.

Pheromones are molecules secreted by organisms that affect the behavior of other members of their species. Behaviors elicited by pheromones include mate attraction, marking territory, leaving trails, and signaling danger (to name only a few). To date, scientific research suggests the existence of human pheromones, but no concrete proof exists.
